

Effect of knitting direction θ_{knit}
(direct FEA sweep, 182 runs; $s_{wale} = s_{course} = 1.0$, $p = 1000$ Pa)

Section curvature $\bar{H}$

Section stress

Curvature anisotropy index

markers = individual runs; line = mean of the two estimates the identity $X_{x=0}(\theta) = X_{y=0}(90^\circ - \theta)$ forces to agree;

band = the gap between them, i.e. the discretisation error of the section extraction on this (non-symmetric) mesh

Motif 1: crown height varies 0.02% over θ (exact 0%); mirror residual $|H_{x=0}(\theta) - H_{y=0}(90^\circ - \theta)|$ 0.11%; $\bar{H}$ varies 0.9%, section stress 22%

Motif 2: crown height varies 0.01% over θ (exact 0%); mirror residual $|H_{x=0}(\theta) - H_{y=0}(90^\circ - \theta)|$ 0.14%; $\bar{H}$ varies 0.7%, section stress 13%
