

Effect of knitting direction θ_{knit} on a non-axisymmetric boundary
(ellipse 2:1 in x, semi-axes 1194 × 598 mm; direct FEA sweep, 182 runs; $s_{wale} = s_{course} = 1.0$, $p = 1000$ Pa)

markers = individual runs; line = Savitzky-Golay trend. No symmetrisation: the identity $X_{x=0}(\theta) = X_{y=0}(90^\circ - \theta)$ used in figM follows from the circle's mirror symmetry and is false here, so the curves are asymmetric about 45° .
Peak-to-peak variation over θ , ellipse vs circle:
Motif 1: h_{crown} 26% (circle 0.02%); $\bar{H}_{x=0}$ 15% (circle 0.93%); $\sigma_{x=0}$ 28% (circle 21.66%)
Motif 2: h_{crown} 14% (circle 0.01%); $\bar{H}_{x=0}$ 7% (circle 0.74%); $\sigma_{x=0}$ 17% (circle 13.49%)
